A function's limit can be one of it's own outputs. When this happens the function called a continuous function.

A Limit of a function is not necessarily one of the function's output values.

A Limit of a function can be one of the function values.

$$\lim_{x \to a} f(x) = f(a)$$

Then we can say that function is continuous at x=a

This means for a function to be continued at x = a

- f(a) must exist
- $\lim_{x\to a} f(x)$ must exist
- $\lim_{x\to a} f(x) = f(a)$

$$\lim_{x \to 1} (x^2 + 2x + 1)$$

This function is continuous.

Algebraic Test for Limits

Graphical Check of Continuity

A graph with no breaks is continuous. Graphically a continuous function should have none of the following.

- Holes A holes in a graph are called removable discontinuity, because they can be determined by studying neighbouring values using Limits.
- Jumps Jump discontinuity, due to a sudden change in values.

-

$$\begin{cases} x^2, & \text{if } x < 1 \\ x + 4, & \text{if } x \ge 1 \end{cases}$$
