Chapter 1

Introduction

Space and time trade-offs are a common occurrence in computer science. The trade-off is a situation where one must sacrifice one aspect of a system to gain another. In computer science, the trade-off is usually between space and time. Space refers to the amount of memory used by a program, while time refers to the amount of time it takes to run the program. In general, the more space a program uses, the faster it will run, and vice versa. The main idea in computing is to pre-process the problem's input at least somewhat and store additional information obtained to speed up solving the problem afterwards. This is called **input enhancement**.

Another technique that exploits space-for-time trade-offs uses extra space to facilitate faster and more flexible access to the data. This is called **prestructuring** .

Chapter 2

Input Enhancement

2.1 Sorting By Counting

Definition 2.1.1: Comparison Counting Sort

For each element x in the input array A, count the number of elements less than x and store this count in an auxiliary array C. Then, use the counts in C to place each element in its correct position in the output array B.

```
Algorithm 1 ComparisonCountingSort (A [0 ... n - 1])
```

```
>
```

- ▶ Sorts an array by comparison counting
- ▶ Input: An array A[0...n-1] of orderable elements
- ▶ Output: Array S[0...n-1] of A's elements sorted in nondecreasing order

```
1: for i \leftarrow 0 to n - 1 do
         Count_i \leftarrow 0
 2:
 3: end for
 4: for i \leftarrow 0 to n-2 do
 5:
         for j \leftarrow i + 1 to n - 1 do
              if A_i > A_j then
 6:
                  Count_i \leftarrow Count_i + 1
 7:
 8:
                  Count_i \leftarrow Count_i + 1
 9:
              end if
10:
11:
         end for
12: end for
13: for i \leftarrow 0 to n-1 do
         S_{\text{Count}_i} \leftarrow A_i
15: end for
16: return S
```

The time complexity of this algorithm is $O(n^2)$, where n is the number of elements in the input array

2.1.1 Distribution Counting Sort

The idea of the comparison counting sort performs better when the elements to be sorted belong to a small set of variables and the number of elements to be sorted is large. Given the array:

13 11 12 13 12	12	12	13	12	11	13	
------------------------	----	----	----	----	----	----	--

Whose elements are known to belong to the set $\{11, 12, 13\}$, and should not be overwritten in the process of sorting. The frequency and distribution arrays are:

Array Values	11	12	13
Frequencies	1	3	2
Distribution values	1	4	6

Now the distribution values indicate the final position of the last element of the corresponding value in the sorted array.

D

Algorithm 2 DistributionCountingSort (A[0...n-1], l, u)

- ▶ Sorts an array of integers from a limited range by distribution counting
- ▶ Input: An array A[0...n-1] of integers between l and u ($l \le u$)
- ▶ Output: Array S[0...n-1] of A's elements sorted in nondecreasing order

```
1: for j \leftarrow 0 to u - l do
         D_i \leftarrow 0
                                                                                                                                    ▶ Initialize frequencies
 3: end for
 4: for i \leftarrow 0 to n - 1 do
         D_{A_i-l} \leftarrow D_{A_i-l} + 1
                                                                                                                                   ▶ Compute frequencies
 6: end for
 7: for j \leftarrow 1 to u - l do
         D_i \leftarrow D_{i-1} + D_i
 9: end for
10: for i \leftarrow n - 1 down to 0 do
         j \leftarrow A_i - l
11:
         S_{D_j-1} \leftarrow A_i
D_j \leftarrow D_j - 1
13:
14: end for
15: return S
```
